Diabetes Insipidus Case Study
Cain. F.
Manchester

This presentation is based on a patient who has been under the care of the Endocrine Team at the Christie Hospital in Manchester since 2008.

He presented with symptoms of excessive thirst and urine frequency following treatment for renal stones.

He has had diagnostic tests which confirmed the diagnosis of Diabetes Insipidus in 2008 with a rare condition identified as the cause; he has remained under the care of the Endocrinologist and Specialist Nurses for management of Hypopituitarism and hormone replacement therapy.

This patient has suffered from psychological problems due the complexity of his health issues, and has been cared for holistically.
As part of the Endocrine Team at the Christie I have performed his investigations including fluid deprivation tests and bone density scans as well as providing education and support for him and his wife.

He continues to have regular follow up in the General Endocrine and Growth Hormone clinics.

The presentation will describe the patients journey from his initial presentation through to diagnosis and long term management.
